## 1 Introduction to algorithm

My algorithm evaluates whether or not the input year is a leap year. It does this by first checking for the input  $\text{mod}(4)$  if this is not 0 the year is not a leap year and that conclusion is printed in the terminal.

If the input  $\text{mod}(4)$  is equal to 0 the algorithm needs to check further and then checks for its  $\text{mod}(100)$  if this is not 0 the year is in fact a leap year and that fact is printed in the terminal. If it were equal to 0 the algorithm needs to check further and then checks if the input  $\text{mod}(400)$  is equal to 0.

if it is input is in fact a leap year and this is printed but if it is not equal to 0 it is not a leap year and this is printed. On the next page you can find a Diagram of the algorithm
